Learning Objectives

• Compare the boiling points of amides with alcohols of similar molar mass.
• Compare the solubilities in water of amides of five or fewer carbon atoms with the solubilities of comparable alkanes and alcohols in water.

With the exception of formamide (HCONH₂), which is a liquid, all simple amides are solids (Table \(\PageIndex{1}\)). The lower members of the series are soluble in water, with borderline solubility occurring in those that have five or six carbon atoms. Like the esters, solutions of amides in water usually are neutral—neither acidic nor basic.

Table \(\PageIndex{1}\): Physical Constants of Some Unsubstituted Amides

The amides generally have high boiling points and melting points. These characteristics and their solubility in water result from the polar nature of the amide group and hydrogen bonding (Figure \(\PageIndex{1}\)). (Similar hydrogen bonding plays a critical role in determining the structure and properties of proteins, deoxyribonucleic acid [DNA], ribonucleic acid [RNA], and other giant molecules so important to life processes.

![Figure](image)

Figure \(\PageIndex{1}\): Hydrogen Bonding in Amides. Amide molecules can engage in hydrogen bonding with water molecules (a). Those amides with a hydrogen atom on the nitrogen atom can also engage in hydrogen bonding (b). Both hydrogen bonding networks extend in all directions.

Concept Review Exercises

1. Which compound has the higher boiling point—pentanamide (CH₃CH₂CH₂CH₂CONH₂) or propyl acetate (CH₃COOCH₂CH₂CH₃)? Explain.

2. Which compound is more soluble in water—propanamide (CH₃CH₂CONH₂) or 1-pentene (CH₂=CHCH₂CH₂CH₃)? Explain.
Answers

1. pentanamide because the nitrogen-to-hydrogen (N–H) and the carbon-to-oxygen double (C=O) bonds can engage in hydrogen bonding; propyl acetate cannot engage in hydrogen bonding

2. propanamide because the N–H and C=O bonds can engage in hydrogen bonding with water; 1-pentene cannot engage in hydrogen bonding with water

Key Takeaways

• Most amides are solids at room temperature; the boiling points of amides are much higher than those of alcohols of similar molar mass.
• Amides of five or fewer carbon atoms are soluble in water?

Exercises

1. Which compound has the higher boiling point—butyramide (CH₃CH₂CH₂CONH₂) or ethyl acetate (CH₃COOCH₂CH₃)? Explain.

2. Which compound has the higher boiling point—butyramide or dimethylacetamide [CH₃CON(CH₃)₂]? Explain.

3. Which compound is more soluble in water—acetamide (CH₃CONH₂) or 1-butene (CH₂=CHCH₂CH₃)? Explain.

4. Which compound is more soluble in water—CH₃CONHCH₃ or 2-methylbutane [CH₃CH(CH₃)CH₂CH₃]? Explain.

Answers

1. butyramide because the nitrogen-to-hydrogen (N–H) and the carbon-to-oxygen double (C=O) bonds can engage in hydrogen bonding; ethyl acetate cannot engage in hydrogen bonding

3. acetamide because the N–H and C=O bonds can engage in hydrogen bonding with water; 1-butene cannot engage in hydrogen bonding with water
