Objectives

After completing this section, you should be able to

1. write an equation to describe the oxidation of an alkylbenzene to a carboxylic acid.
2. identify the reagents required to oxidize a given alkylbenzene to a carboxylic acid.
3. identify the product formed from the side-chain oxidation of a given alkylbenzene.
4. identify the aromatic compound needed to produce a given carboxylic acid through side-chain oxidation.
5. write the equation for the bromination of an alkylbenzene side chain.
6. identify the reagents and conditions necessary to bring about bromination in the side chain of an alkylbenzene.
7. identify the product formed when a given alkylbenzene undergoes side-chain bromination.
8. identify the alkylbenzene needed to prepare a given benzylic bromide by radical substitution.
9. write the mechanism for the radical substitution at the benzylic position of an alkylbenzene.
10. explain the stability of benzylic radicals in terms of resonance, and draw the resonance contributors of a given benzylic radical.
11. explain, and illustrate with appropriate examples, the importance of benzylic bromides as intermediates in organic syntheses.
12. arrange a given series of radicals (including benzylic type radicals) in order of increasing or decreasing stability. (Review Section 10.3 if necessary.)

Key Terms

Make certain that you can define, and use in context, the key terms below.

- benzylic oxidation
- benzylic position
- side-chain oxidation

Study Notes

As you can see from the examples, no matter what the length of the alkyl group in the arene substrate, the product is always a one-carbon carboxyl group. Thus, the benzylic carbon atom has been oxidized and the term *benzylic oxidation* is appropriate. The term *side-chain oxidation* is also commonly used.

In alkylbenzenes, the carbon atom which is attached to the aromatic ring is particularly reactive. Reactions taking place at this carbon atom are said to occur at the *benzylic position*.

You may wish to review Section 10.3 to remind yourself about allylic bromination using N-bromosuccinimide.

Benzylic halides undergo the typical reactions of alkyl halides; thus, you can expect to see such compounds used frequently in multistep syntheses.

Note that we have adopted the terminology given below.

Any compound of the type
organobenzene with halogen on first carbon external to the ring
(where X = halogen) will be referred to as a “benzylic halide.”

Compounds of the type
methyl hydrogen of toluene replaced by a halogen atom
are actually called benzyl chloride, benzyl bromide, etc.

The compound
methyl hydrogen of toluene replaced by a hydroxide group
is called benzyl alcohol.

**Oxidation of Alkyl Side-Chains**

**Edit section**

The benzylic hydrogens of alkyl substituents on a benzene ring are activated toward free radical attack, as noted earlier. Furthermore, $S_N1$, $S_N2$ and E1 reactions of benzylic halides, show enhanced reactivity, due to the adjacent aromatic ring. The possibility that these observations reflect a general benzylic activation is supported by the susceptibility of alkyl side-chains to oxidative degradation, as shown in the following examples (the oxidized side chain is colored). Such oxidations are normally effected by hot acidic permanganate solutions, but for large scale industrial operations catalyzed air-oxidations are preferred. Interestingly, if the benzylic position is completely substituted this oxidative degradation does not occur (second equation, the substituted benzylic carbon is colored blue).

$$C_6H_5–CH_2CH_2CH_2CH_3 + KMnO_4 + H_3O^{(+)} \& \text{heat} \rightarrow C_6H_5–CO_2H + CO_2$$

$$p-(CH_3)_3C–C_6H_4–CH_3 + KMnO_4 + H_3O^{(+)} \& \text{heat} \rightarrow p-(CH_3)_3C–C_6H_4–CO_2H$$

These equations are not balanced. The permanganate oxidant is reduced, usually to Mn(IV) or Mn(II). Two other examples of this reaction are given below, and illustrate its usefulness in preparing substituted benzoic acids.
Bromination of the Benzylic Carbon

The benzylic C-H bonds weaker than most $sp^3$ hybridized C-H. This is because the radical formed from homolysis is resonance stabilized.

Because of the weak C-H bonds, benzylic hydrogens can form benzylic halides under radical conditions.

NBS as a Bromine Source

NBS (N-bromosuccinimide) is the most commonly used reagent to produce low concentrations of bromine. When suspended in tetrachloride (CCl₄), NBS reacts with trace amounts of HBr to produce a low enough concentration of bromine to facilitate the allylic bromination reaction.
Allylic Bromination Mechanism

Step 1: Initiation

Once the pre-initiation step involving NBS produces small quantities of Br$_2$, the bromine molecules are homolytically cleaved by light to produce bromine radicals.

Step 2 and 3: Propagation

Step 4: Termination

Exercises

Questions

Q16.9.1

Predict the products.
Q16.9.2

Consider a benzyl radical. Would it be more stable than an alkyl radical? Explain.

Q16.9.3

How would you make the following molecule?

Solutions

S16.9.1

The second one leads to no reaction because it requires a hydrogen just off the phenyl ring.
Yes it would be more stable than an alkyl radical, consider the pi system able to stabilize through resonance.

The following is just one possibility.
