Learning Objectives

• Describe the fundamental aspects of titrations and gravimetric analysis.
• Perform stoichiometric calculations using typical titration and gravimetric data.

In the 18th century, the strength (actually the concentration) of vinegar samples was determined by noting the amount of potassium carbonate, \( \text{K}_2\text{CO}_3 \), which had to be added, a little at a time, before bubbling ceased. The greater the weight of potassium carbonate added to reach the point where the bubbling ended, the more concentrated the vinegar.

We now know that the effervescence that occurred during this process was due to reaction with acetic acid, \( \text{CH}_3\text{CO}_2\text{H} \), the compound primarily responsible for the odor and taste of vinegar. Acetic acid reacts with potassium carbonate according to the following equation:

\[
\text{\text{CH}_3\text{CO}_2\text{H}}(\text{aq}) + \text{\text{K}_2\text{CO}_3}(\text{s}) \rightarrow \text{\text{KCH}_3\text{CO}_3}(\text{aq}) + \text{\text{CO}_2}(\text{g}) + \text{\text{H}_2\text{O}}(\text{l})
\]

The bubbling was due to the production of \( \text{CO}_2 \).

The test of vinegar with potassium carbonate is one type of quantitative analysis—the determination of the amount or concentration of a substance in a sample. In the analysis of vinegar, the concentration of the solute (acetic acid) was determined from the amount of reactant that combined with the solute present in a known volume of the solution. In other types of chemical analyses, the amount of a substance present in a sample is determined by measuring the amount of product that results.

**Titration**

The described approach to measuring vinegar strength was an early version of the analytical technique known as titration analysis. A typical titration analysis involves the use of a buret (Figure 1) to make incremental additions of a solution containing a known concentration of some substance (the titrant) to a sample solution containing the substance whose concentration is to be measured (the analyte). The titrant and analyte undergo a chemical reaction of known stoichiometry, and so measuring the volume of titrant solution required for complete reaction with the analyte (the equivalence point of the titration) allows calculation of the analyte concentration. The equivalence point of a titration may be detected visually if a distinct change in the appearance of the sample solution accompanies the completion of the reaction. The halt of bubble formation in the classic vinegar analysis is one such example, though, more commonly, special dyes called indicators are added to the sample solutions to impart a change in color at or very near the equivalence point of the titration. Equivalence points may also be detected by measuring some solution property that changes in a predictable way during the course of the titration. Regardless of the approach taken to detect a titration's equivalence point, the volume of titrant actually measured is called the end point. Properly designed titration methods typically ensure that the difference between the equivalence and end points is negligible. Though any type of chemical reaction may serve as the basis for a titration analysis, the three described in this chapter (precipitation, acid-base, and redox) are most common. Additional details regarding titration analysis are provided in the chapter on acid-base equilibria.
Figure \(\PageIndex{1}\): (a) A student fills a buret in preparation for a titration analysis. (b) A typical buret permits volume measurements to the nearest 0.1 mL. (credit a: modification of work by Mark Blaser and Matt Evans; credit b: modification of work by Mark Blaser and Matt Evans)

Example \(\PageIndex{1}\): Titration Analysis

The end point in a titration of a 50.00-mL sample of aqueous HCl was reached by addition of 35.23 mL of 0.250 M NaOH titrant. The titration reaction is:

\[
\ce{HCl(aq) + NaOH(aq) -> NaCl(aq) + H2O(l)}
\]

What is the molarity of the HCl?

**Solution**

As for all reaction stoichiometry calculations, the key issue is the relation between the molar amounts of the chemical species of interest as depicted in the balanced chemical equation. The approach outlined in previous modules of this chapter is followed, with additional considerations required, since the amounts of reactants provided and requested are expressed as solution concentrations.

For this exercise, the calculation will follow the following outlined steps:

\[
\text{Moles of NaOH} = \frac{35.23\times 10^{-3}\text{ L}}{1000\times 0.250\text{ mol/L}} = 8.81\times 10^{-5}\text{ mol}
\]

The molar amount of HCl is calculated to be:

\[
\text{Moles of HCl} = \frac{8.81\times 10^{-5}\text{ mol NaOH}}{1\text{ mol HCl}: 1\text{ mol NaOH}} = 8.81\times 10^{-5}\times 10^2\text{ mol HCl} = 8.81\times 10^{-3}\text{ mol HCl}
\]
Using the provided volume of HCl solution and the definition of molarity, the HCl concentration is:

\[
M = \frac{\text{mol HCl}}{\text{L solution}}
\]

\[
M = \frac{8.81 \times 10^{-3} \text{ mol HCl}}{50.00 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}}}
\]

\[
M = 0.176 \text{ M}
\]

Note: For these types of titration calculations, it is convenient to recognize that solution molarity is also equal to the number of millimoles of solute per milliliter of solution:

\[
M = \frac{\text{mol solute}}{\text{L solution}} \times \frac{\frac{10^3 \text{ mmol}}{\text{mol}}}{\frac{10^3 \text{ mL}}{\text{L}}}
\]

Using this version of the molarity unit will shorten the calculation by eliminating two conversion factors:

\[
\frac{35.23 \text{ mL NaOH} \times \frac{0.250 \text{ mmol NaOH}}{\text{mL NaOH}} \times \frac{1 \text{ mmol HCl}}{1 \text{ mmol NaOH}}}{50.00 \text{ mL solution}} = 0.176 \text{ M HCl}
\]

Exercise \(\PageIndex{1}\)

A 20.00-mL sample of aqueous oxalic acid, H\(_2\)C\(_2\)O\(_4\), was titrated with a 0.09113-M solution of potassium permanganate, KMnO\(_4\).

\[
\text{2MnO}_4^-(aq) + 5\text{H}_2\text{C}_2\text{O}_4(aq) + 6\text{H}^+(aq) \rightarrow 10\text{CO}_2(g) + 2\text{Mn}^{2+}(aq) + 8\text{H}_2\text{O}(l)
\]

A volume of 23.24 mL was required to reach the end point. What is the oxalic acid molarity?

**Answer**

0.2648 M

---

**Gravimetric Analysis**

A gravimetric analysis is one in which a sample is subjected to some treatment that causes a change in the physical state of the analyte that permits its separation from the other components of the sample. Mass measurements of the sample, the isolated analyte, or some other component of the analysis system, used along with the known stoichiometry of the compounds involved, permit calculation of the analyte concentration. Gravimetric methods were the first techniques used for quantitative chemical analysis, and they remain important tools in the modern chemistry laboratory.

The required change of state in a gravimetric analysis may be achieved by various physical and chemical processes. For example, the moisture (water) content of a sample is routinely determined by measuring the mass of a sample before and after it is subjected to a controlled heating process that evaporates the water. Also common are gravimetric techniques in which the analyte is subjected to a precipitation reaction of the sort described earlier in this chapter. The precipitate is typically isolated from the reaction mixture by filtration, carefully dried, and then weighed (Figure \(\PageIndex{2}\)). The mass of the precipitate may then be used, along with relevant stoichiometric relationships, to calculate analyte concentration.
Figure \(\PageIndex{2}\): Precipitate may be removed from a reaction mixture by filtration.

Example \(\PageIndex{2}\): Gravimetric Analysis

A 0.4550-g solid mixture containing MgSO\(_4\) is dissolved in water and treated with an excess of Ba(NO\(_3\))\(_2\), resulting in the precipitation of 0.6168 g of BaSO\(_4\).

\[
\text{MgSO}_4(aq) + \text{Ba(NO}_3)_2(aq) \rightarrow \text{BaSO}_4(s) + \text{Mg(NO}_3)_2(aq)
\]

What is the concentration (percent) of MgSO\(_4\) in the mixture?

**Solution**

The plan for this calculation is similar to others used in stoichiometric calculations, the central step being the connection between the moles of BaSO\(_4\) and MgSO\(_4\) through their stoichiometric factor. Once the mass of MgSO\(_4\) is computed, it may be used along with the mass of the sample mixture to calculate the requested percentage concentration.
The mass of MgSO$_4$ that would yield the provided precipitate mass is
\[
0.6168 \text{ g BaSO}_4 \times \frac{1 \text{ mol BaSO}_4}{233.43 \text{ g BaSO}_4} \times \frac{1 \text{ mol MgSO}_4}{1 \text{ mol BaSO}_4} \times \frac{120.37 \text{ g MgSO}_4}{1 \text{ mol MgSO}_4} = 0.3181 \text{ g MgSO}_4
\]

The concentration of MgSO$_4$ in the sample mixture is then calculated to be
\[
\text{percent MgSO}_4 = \frac{\text{mass MgSO}_4}{\text{mass sample}} \times 100\% \\
\frac{0.3181 \text{ g}}{0.4550 \text{ g}} \times 100\% = 69.91\%
\]

Exercise \(\PageIndex{2}\))

What is the percent of chloride ion in a sample if 1.1324 g of the sample produces 1.0881 g of AgCl when treated with excess Ag$^+$?
\[
\text{Ag}^+(aq) + \text{Cl}^-(aq) \rightarrow \text{AgCl}(s)
\]

Answer

23.76%

---

**Combustion Analysis**

The elemental composition of hydrocarbons and related compounds may be determined via a gravimetric method known as combustion analysis. In a combustion analysis, a weighed sample of the compound is heated to a high temperature under a stream of oxygen gas, resulting in its complete combustion to yield gaseous products of known identities. The complete combustion of hydrocarbons, for example, will yield carbon dioxide and water as the only products. The gaseous combustion products are swept through separate, preweighed collection devices containing compounds that selectively absorb each product (Figure \(\PageIndex{3}\)). The mass increase of each device corresponds to the mass of the absorbed product and may be used in an appropriate stoichiometric calculation to derive the mass of the relevant element.
Figure (PageIndex{3}): This schematic diagram illustrates the basic components of a combustion analysis device for determining the carbon and hydrogen content of a sample.

Example (PageIndex{3}): Combustion Analysis

Polyethylene is a hydrocarbon polymer used to produce food-storage bags and many other flexible plastic items. A combustion analysis of a 0.00126-g sample of polyethylene yields 0.00394 g of CO\(_2\) and 0.00161 g of H\(_2\)O. What is the empirical formula of polyethylene?

Solution

The primary assumption in this exercise is that all the carbon in the sample combusted is converted to carbon dioxide, and all the hydrogen in the sample is converted to water:

\[
\text{C}_x\text{H}_y(s) + \text{O}_2(g) \rightarrow x\text{CO}_2(g) + \frac{y}{2}\text{H}_2\text{O}(g)
\]

Note that a balanced equation is not necessary for the task at hand. To derive the empirical formula of the compound, only the subscripts \(x\) and \(y\) are needed.

First, calculate the molar amounts of carbon and hydrogen in the sample, using the provided masses of the carbon dioxide and water, respectively. With these molar amounts, the empirical formula for the compound may be written as described in the previous chapter of this text. An outline of this approach is given in the following flow chart:

\[
\text{mol CO}_2 = 0.00394\text{ g CO}_2 \times \frac{1\text{ mol CO}_2}{44.01\text{ g/mol}} \times \frac{1\text{ mol C}}{1\text{ mol CO}_2} = 8.95 \times 10^{-5}\text{ mol C}
\]

\[
\text{mol H} = 0.00161\text{ g H}_2\text{O} \times \frac{1\text{ mol H}_2\text{O}}{18.02\text{ g/mol}} \times \frac{2\text{ mol H}}{1\text{ mol H}_2\text{O}} = 1.79 \times 10^{-4}\text{ mol H}
\]
The empirical formula for the compound is then derived by identifying the smallest whole-number multiples for these molar amounts. The H-to-C molar ratio is

\[
\frac{mol\: H}{mol\: C} = \frac{1.79 \times 10^{-4}\: mol\: H}{8.95 \times 10^{-5}\: mol\: C} = \frac{2\: mol}{1\: mol}
\]

and the empirical formula for polyethylene is CH₂.

Exercise \(\PageIndex{3}\)

A 0.00215-g sample of polystyrene, a polymer composed of carbon and hydrogen, produced 0.00726 g of CO₂ and 0.00148 g of H₂O in a combustion analysis. What is the empirical formula for polystyrene?

**Answer**

CH

---

**Summary**

The stoichiometry of chemical reactions may serve as the basis for quantitative chemical analysis methods. Titrations involve measuring the volume of a titrant solution required to completely react with a sample solution. This volume is then used to calculate the concentration of analyte in the sample using the stoichiometry of the titration reaction. Gravimetric analysis involves separating the analyte from the sample by a physical or chemical process, determining its mass, and then calculating its concentration in the sample based on the stoichiometry of the relevant process. Combustion analysis is a gravimetric method used to determine the elemental composition of a compound by collecting and weighing the gaseous products of its combustion.

---

**Glossary**

**analyte**

chemical species of interest

**buret**

device used for the precise delivery of variable liquid volumes, such as in a titration analysis

**combustion analysis**

gravimetric technique used to determine the elemental composition of a compound via the collection and weighing of its gaseous combustion products

**end point**

measured volume of titrant solution that yields the change in sample solution appearance or other property expected for stoichiometric equivalence (see equivalence point)

**equivalence point**

volume of titrant solution required to react completely with the analyte in a titration analysis; provides a stoichiometric amount of titrant for the sample’s analyte according to the titration reaction
gravimetric analysis
quantitative chemical analysis method involving the separation of an analyte from a sample by a physical or chemical process and subsequent mass measurements of the analyte, reaction product, and/or sample

indicator
substance added to the sample in a titration analysis to permit visual detection of the end point

quantitative analysis
the determination of the amount or concentration of a substance in a sample

titrant
solution containing a known concentration of substance that will react with the analyte in a titration analysis

titration analysis
quantitative chemical analysis method that involves measuring the volume of a reactant solution required to completely react with the analyte in a sample
