Torsional strain or eclipsing strain is the increase in potential energy of a molecule due to repulsion between electrons in bonds that do not share an atom.

Consider two conformations of ethane:

![Conformations of ethane](image)

The smallest dihedral angle is 60° in 1; it is 0° in 2. Thus, two C-H bonds not sharing a carbon atom that are closest to each other (ex: C-H₁ and C-H₄) are closer in 2 than in 1. The repulsion between electrons in bonds that do not share a carbon atom is, therefore, greater in 2 than in 1. Consequently, torsional strain is greater in 2 than in 1.

- see also angle strain, steric strain
