Learning Objectives

- To understand Enthalpies of Solution and be able to use them to calculate the Heat absorbed or emitted when making solutions.

**Enthalpies of Solution and Dilution**

Physical changes, such as melting or vaporization, and chemical reactions, in which one substance is converted to another, are accompanied by changes in enthalpy. Two other kinds of changes that are accompanied by changes in enthalpy are the dissolution of solids and the dilution of concentrated solutions.

The dissolution of a solid can be described as follows:

\[
solute(s) + solvent(l) \rightarrow solution(l) \tag{15.6.1}
\]

The values of \( \Delta H_{\text{soln}} \) for some common substances are given in Table 15.6.1. The sign and the magnitude of \( \Delta H_{\text{soln}} \) depend on specific attractive and repulsive interactions between the solute and the solvent; these factors were discussed in Chapter 12. When substances dissolve, the process can be either exothermic (\( \Delta H_{\text{soln}} < 0 \)) or endothermic (\( \Delta H_{\text{soln}} > 0 \)), as you can see from the data in Table 15.6.1.

**Table 15.6.1 Enthalpies of Solution at 25°C of Selected Ionic Compounds in Water (in kJ/mol)**

Substances with large positive or negative enthalpies of solution have commercial applications as instant cold or hot packs. Single-use versions of these products are based on the dissolution of either calcium chloride (CaCl₂, ΔH_{soln} = −81.3 kJ/mol) or ammonium nitrate (NH₄NO₃, ΔH_{soln} = +25.7 kJ/mol). Both types consist of a plastic bag that contains about 100 mL of water plus a dry chemical (40 g of CaCl₂ or 30 g of NH₄NO₃) in a separate plastic pouch. When the pack is twisted or struck sharply, the inner plastic bag of water ruptures, and the salt dissolves in the water. If the salt is CaCl₂, heat is released to produce a solution with a temperature of about 90°C; hence the product is an “instant hot compress.” If the salt is NH₄NO₃, heat is absorbed when it dissolves, and the temperature drops to about 0° for an “instant cold pack.”

A similar product based on the precipitation of sodium acetate, not its dissolution, is marketed as a reusable hand warmer (Figure 15.6.1). At high temperatures, sodium acetate forms a highly concentrated aqueous solution. With cooling, an unstable supersaturated solution containing excess solute is formed. When the pack is agitated, sodium acetate trihydrate [CH₃CO₂Na·3H₂O] crystallizes, and heat is evolved:

\[
\text{Na}^+ (\text{aq}) + \text{CH}_3\text{CO}_2^- (\text{aq}) + \text{H}_2\text{O} (\text{l}) \rightarrow \text{CH}_3\text{CO}_2\text{Na} \cdot \text{H}_2\text{O} (\text{s}) \quad \Delta H = -\Delta H_{\text{soln}} = -19.7 \text{ kJ/mol}
\]

A bag of concentrated sodium acetate solution can be carried until heat is needed, at which time vigorous agitation induces crystallization and heat is released. The pack can be reused after it is immersed in hot water until the sodium acetate redissolves.

![Figure 15.6.2 An Instant Hot Pack Based on the Crystallization of Sodium Acetate](Image)
The hot pack is at room temperature prior to agitation (left). Because the sodium acetate is in solution, you can see the metal disc inside the pack.
After the hot pack has been agitated, the sodium acetate crystallizes (right) to release heat. Because of the mass of white sodium acetate that has crystallized, the metal disc is no longer visible.

The amount of heat released or absorbed when a substance is dissolved is not a constant; it depends on the final concentration of the solute. The $\Delta H_{\text{soln}}$ values given previously and in Table 15.6.1 for example, were obtained by measuring the enthalpy changes at various concentrations and extrapolating the data to infinite dilution.

Because $\Delta H_{\text{soln}}$ depends on the concentration of the solute, diluting a solution can produce a change in enthalpy. If the initial dissolution process is exothermic ($\Delta H < 0$), then the dilution process is also exothermic. This phenomenon is particularly relevant for strong acids and bases, which are often sold or stored as concentrated aqueous solutions. If water is added to a concentrated solution of sulfuric acid (which is 98% $\text{H}_2\text{SO}_4$ and 2% $\text{H}_2\text{O}$) or sodium hydroxide, the heat released by the large negative $\Delta H$ can cause the solution to boil. Dangerous spattering of strong acid or base can be avoided if the concentrated acid or base is slowly added to water, so that the heat liberated is largely dissipated by the water. Thus you should never add water to a strong acid or base; a useful way to avoid the danger is to remember: Add water to acid and get blasted!

Summary

The enthalpy of solution ($\Delta H_{\text{soln}}$) is the heat released or absorbed when a specified amount of a solute dissolves in a certain quantity of solvent at constant pressure.

Key Takeaway

- Enthalpy is a state function whose change indicates the amount of heat transferred from a system to its surroundings or vice versa, at constant pressure.

Conceptual Problems

1. Describe the distinction between $\Delta H_{\text{soln}}$ and $\Delta H_f$.

2. Does adding water to concentrated acid result in an endothermic or an exothermic process?

3. The following table lists $\Delta H^0_{\text{soln}}$ values for some ionic compounds. If 1 mol of each solute is dissolved in 500 mL of water, rank the resulting solutions from warmest to coldest.
