Dietary intake of vegetable oils and hydrogenated vegetable oils has significant health effects. Not only do they have about twice as many calories per gram as sugars and proteins, but they have long term effects on circulatory system health. Crisco®️, with saturated oils, may not be as healthy as olive oil, with more unsaturated oils. Crisco contains hydrogenated vegetable oil[1]

olive oil is 55-83% oleic acid[2]

To understand these effects, we need to look at the structure of triglycerides. The triglyceride [1] is an important part of the blood test done with an annual physical exam.

Triglycerides
Vegetable oils are all triglycerides, which contain a glycerol (three carbon "backbone" with 3 long chain "fatty acids" attached through ester linkages, as in the figure below. The actual shape is shown in the Jmol model, which can be rotated with the mouse.

A triglyceride, overall unsaturated, with the glycerol "backbone" on the left, and saturated palmitic acid, monounsaturated oleic acid, and polyunsaturated alpha-linolenic acid.

The long chain fatty acids may be saturated with hydrogen atoms, in which case they have all single bonds like the top fatty acid in the Figure (which is palmitic acid). If they have fewer hydrogen atoms, they are unsaturated and have double bonds like the middle fatty acid in the Figure (which is oleic acid). The bottom fatty acid is polyunsaturated, with multiple double bonds (it is linolenic acid). Various cooking oils have known concentrations of saturated and unsaturated fatty acids.

Saturated vs. Unsaturated vs. Trans Fatty Acids

Generally, triglycerides with more unsaturated fatty acid substituents are more healthful, but food companies hydrogenate them to make them solid saturated fats (like margarine or Crisco), and to reduce the tendency to spoil. Unsaturated fats have kinks in their molecular structures that reduce the tendency for them to cause arthrosclerosis (clogged arteries), pretty much for the same reason that kinks reduce the tendency to pack efficiently and form solids. Saturated fats have more linear fatty acid chains that pack well and solidify easily. Compare the Jmol models of saturated palmitic acid and unsaturated oleic acid below. Partial hydrogenation of polyunsaturated fats also produces trans-fatty acids, which have structures like saturated fats and consequently are as unhealthy (see Elaidic Acid Below):
Elaidic Acid, $\text{C}_{18}\text{H}_{34}\text{O}_2$

*Trans*-fatty acids have the hydrogens on opposite sides of the C=C double bond, like this

\[ \text{\text{\begin{center}
\begin{tabular}{c}
\end{tabular}
\end{center}}} \]

while *cis*-fatty acids have the hydrogen atoms on the same side, like this

\[ \text{\text{\begin{center}
\begin{tabular}{c}
\end{tabular}
\end{center}}} \]

**Composition of Crisco, "partially hydrogenated" vegetable oil**

As of 2010 Crisco is made of soybean oil, fully hydrogenated cottonseed oil, and partially hydrogenated soybean and cottonseed oils. According to the product information label, one 12 g serving of Crisco contains 3 g of saturated fat, 0g of trans fat, 6 g of polyunsaturated fat, and 2.5 g of monounsaturated fat.\(^3\) Notice that the fat masses don't add up\(^4\) because the weights of glycerol are not included in the separately listed components. *Trans* fatty acids are now recognized as a major dietary risk factor for cardiovascular diseases, and the US FDA has revised food labeling requirements to include trans fats.\(^5\)

The composition of the soybean oil in Crisco is shown below.\(^6\)

Quite often a mixture of two or more products is formed in a chemical reaction. For example, when a vegetable oil like palm oil is hydrogenated, we might want to make just mono-unsaturated products. But the many triglycerides it contains with varied fatty acid chains. No single process could work for all of them. Suppose we start with just one possible palm oil molecule, a glycerol with 2 linolenic acid, and 1 linoleic acid substituents (we'll abbreviate it GLLL). The desired product might be the oil with three oleic acid substituents (we'll abbreviate it GOOO, which also might be a good description of it) so the equation is:

\[
(C_{18}H_{29}O_2)CH_2CH(C_{18}H_{31}O_2)CH_2 \rightarrow (C_{18}H_{33}O_2)CH_2CH(C_{18}H_{33}O_2)CH_2(C_{18}H_{33}O_2)
\]

"GLLL" + 5 H₂ → "GOOO"

A large excess of hydrogen is usually present under pressure, with a palladium or "Raney Nickel" catalyst. A large number of products is obtained, including completely saturated fats like Stearin (glyceryl tristearate),

[![](image1.png)](image1.png)

and trans fats. The products are usually analyzed by converting the oils to simpler (methyl) esters and running a gas chromatogram.

The effectiveness of the reaction is usually evaluated in terms of percent yield of the desired product. A theoretical yield is calculated by assuming that all the limiting reagent is converted to product. The experimentally determined mass

<table>
<thead>
<tr>
<th>Fatty Acid</th>
<th>Formula</th>
<th>Percent Yield</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linoleic Acid</td>
<td>C₁₈H₃₂O₂</td>
<td>51</td>
</tr>
<tr>
<td>Linolenic Acid</td>
<td>C₁₈H₃₀O₂</td>
<td>7-10</td>
</tr>
<tr>
<td>Other</td>
<td></td>
<td>2-5</td>
</tr>
</tbody>
</table>
of product is then compared to the theoretical yield and expressed as a percentage:

**EXAMPLE 1** Suppose a hydrogenation of 100.0 g of \((C_{18}H_{29}O_2)CH_2CH(C_{18}H_{29}O_2)CH_2-(C_{18}H_{31}O_2)\), abbreviated "GLLL" \((M = 875.4 \text{ g/mol})\) is carried out with 2.000 g \(H_2\), sealed in a high pressure steel reaction vessel with a catalyst at 55°C. The products include 90.96 g \((C_{18}H_{33}O_2)CH_2CH(C_{18}H_{33}O_2)CH_2-(C_{18}H_{33}O_2)\), abbreviated "GOOO" \((M = 885.5 \text{ g/mol})\). Calculate the percent yield.

**Solution** We must calculate the theoretical yield of \((C_{18}H_{33}O_2)CH_2CH(C_{18}H_{33}O_2)CH_2-(C_{18}H_{33}O_2)\), and to do this, we must first discover whether \((C_{18}H_{29}O_2)CH_2CH(C_{18}H_{29}O_2)CH_2-(C_{18}H_{31}O_2)\) or \(H_2\) is the limiting reagent. For the balanced equation above,

The stoichiometric ratio of the reactants is

**Now, the initial amounts of the two reagents are and**

The ratio of initial amounts is thus

Since this ratio is less than

, there is an excess of \(H_2\). GLLL is the limiting reagent. Accordingly we must use 0.1142 mol GLLL and 0.5712 mol \(H_2\) (rather than 0.9921 mol \(H_2\)) to calculate the theoretical yield of \((C_{18}H_{33}O_2)CH_2CH(C_{18}H_{33}O_2)CH_2-(C_{18}H_{33}O_2)\), or "GOOO". We then have

so that

We can organize these calculations in a table:

<table>
<thead>
<tr>
<th>((C_{18}H_{29}O_2)CH_2CH(C_{18}H_{29}O_2)CH_2-(C_{18}H_{31}O_2) &quot;GLLL&quot;)</th>
<th>(\rightarrow)</th>
<th>((C_{18}H_{33}O_2)CH_2CH(C_{18}H_{33}O_2)CH_2-(C_{18}H_{33}O_2) &quot;GOOO&quot;)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(m, \text{ g})</td>
<td>100.0 g</td>
<td>2.000 g</td>
</tr>
<tr>
<td>(90.96 \text{ g})</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The percent yield is then
